

Real subject-6 transfer: agreement is not accuracy

PVI pseudo-reference – not ground truth

Task. Real subject-6 voltages, held-out trials 10–11. There is **no anatomical ground truth** on a real limb. Correlation is versus the PVI Newton pseudo-reference: it measures agreement with the existing inverse, not anatomical correctness.

Method	Corr. vs PVI ↑	Mean per-sample corr. ↑	Voltage RMS ↓
Iterative LM stage 1 matches PVI by construction	1.000	1.000	6.66e-6
Selected GCNM stage 1	0.604	0.443	1.68e-5
Selected GCNM stage 2	0.169	0.275	2.63e-5

Takeaway. Stage 1 sits near the PVI inverse and lowers its physical voltage residual; stage 2 drifts away and raises it. This is direct evidence of synthetic-to-real distribution shift—not a verdict on which image is more anatomically correct.

↑ means greater agreement with the pseudo-reference, not greater anatomical accuracy. Bold = best value in each displayed column.
